

GS130 / GS230 SUPERCAPACITOR

Datasheet Rev 4.3, July 2018

This Datasheet should be read in conjunction with the CAP-XX Supercapacitors Product Guide which contains information common to our product lines.

Electrical Specifications

The GS130 is a single cell supercapacitor. The GS230 is a dual cell supercapacitor with two GS130 cells in series, so GS230 capacitance = Capacitance of GS130/2 and GS230 ESR = 2 x GS130 ESR.

Table 1: Absolute Maximum Ratings

| Parameter | Name | | Conditions | Min | Typical | Max | Units |
|------------------|-------------------|-------|------------|-----|---------|------|-------|
| Terminal Voltage | V _{peak} | GS130 | | 0 | | 2.75 | V |
| | | GS230 | | | | 5.5 | |
| Temperature | T _{max} | | | -40 | | +70 | °C |

Table 2: Electrical Characteristics

| Parameter | Name | | Conditions | Min | Typical | Max | Units |
|---------------------------|------------------|-------|-------------------|------|---------|------|-------|
| Terminal Voltage | V _n | GS130 | | 0 | | 2.5 | V |
| | | GS230 | | 0 | | 5.0 | |
| Capacitance | C | GS130 | DC, 23°C | 1920 | 2400 | 2880 | mF |
| | | GS230 | | 960 | 1200 | 1440 | |
| ESR | ESR | GS130 | DC, 23°C | | 15 | 18 | mΩ |
| | | GS230 | | | 25 | 30 | |
| Leakage Current | I _L | | 2.3V, 23°C 120hrs | | 2.5 | 5 | μA |
| RMS Current | I _{RMS} | | 23°C | | | 8 | A |
| Peak Current ¹ | I _P | | 23°C | | | 30 | A |

¹Non-repetitive current, single pulse to discharge fully charged supercapacitor.

Table 3: Thickness

| | | | | | |
|--------|-------|---|--------|-------|--|
| GS130F | 1.9mm | No adhesive tape on underside of the supercapacitor | GS130G | 2.0mm | Adhesive tape on underside, release tape removed |
| GS230F | 3.9mm | | GS230G | 4.0mm | |

Definition of Terms

In its simplest form, the Equivalent Series Resistance (ESR) of a capacitor is the real part of the complex impedance. In the time domain, it can be found by applying a step discharge current to a charged cell as in Fig. 1. In this figure, the supercapacitor is pre-charged and then discharged with a current pulse, $I = 1\text{A}$ for duration 0.01 sec .

Figure 1: Effective capacitance, instantaneous capacitance and ESR for a GS230

The ESR is found by dividing the instantaneous voltage step (ΔV) by I . In this example $= (4.49V - 4.475V)/1A = 15m\Omega$.

The instantaneous capacitance (C_i) can be found by taking the inverse of the derivative of the voltage, and multiplying it by I .

The effective capacitance for a pulse of duration Δt_n , $C_e(\Delta t_n)$ is found by dividing the total charge removed from the capacitor (ΔQ_n) by the voltage lost by the capacitor (ΔV_n). For constant current $C_e(\Delta t_n) = I \times \Delta t_n / \Delta V_n$. C_e increases as the pulse width increases and tends to the DC capacitance value as the pulse width becomes very long (~ 10 secs). After 2msecs, Fig 1 shows the voltage drop $V_{2ms} = (4.475V - 4.461V) = 14mV$. Therefore $C_e(2ms) = 1A \times 2ms / 14mV = 142mF$. After 10ms, the voltage drop $= 4.475V - 4.445V = 30mV$. Therefore $C_e(10ms) = 1A \times 10ms / 30mV = 333mF$. The DC capacitance of a GS230 = 1.2 F. Note that ΔV , or IR drop, is not included because very little charge is removed from the capacitor during this time. C_e shows the time response of the capacitor and it is useful for predicting circuit behavior in pulsed applications.

Measurement of DC Capacitance

Fig 2: Measurement of DC Capacitance for a GS230

Fig 2 shows the measurement of DC capacitance by drawing a constant 100mA current from a fully charged supercapacitor and measuring the time taken to discharge from 1.5V to 0.5V for a single cell, or from 3V to 1V for a dual cell supercapacitor. In this case, $C = 0.1A \times 24.9s / 2V = 1245mF$, which is well within the 1200mF +/- 20% tolerance for a GS230 cell.

Measurement of ESR

Fig 3: Measurement of ESR for a GS230

Fig 3 shows DC measurement of ESR by applying a step load current to the supercapacitor and measuring the resulting voltage drop. CAP-XX waits for a delay of 50μs after the step current is applied to ensure the voltage and current have settled. In this case the ESR is measured as $20mV/1A = 20m\Omega$.

Effective Capacitance (Ceff)

Figure 4: Effective Capacitance

Fig 4 shows the effective capacitance for the GS130, GS230 @ 23°C. This shows that for a 1ms PW, you will measure 13% of DC capacitance or 312mF for a GS130 or 156mF for a GS230. At 10ms, you will measure 31% of the DC capacitance, and at 100ms you will measure 72% of DC capacitance. Ceffective is a time domain representation of the supercapacitor's frequency response. If, for example, you were calculating the voltage drop if the supercapacitor was supporting 1A for 10ms, then you would use the $C_{eff}(10\text{msecs}) = 31\%$ of DC capacitance = 372mF for a GS230, so $V_{drop} = 1A \times ESR + 1A \times \text{duration}/C = 1A \times 25m\Omega + 1A \times 10ms / 372mF = 52mV$. The next section on pulse response shows how the effective capacitance is sufficient for even short pulse widths.

Pulse Response

Fig 5 shows that the GS230 supercapacitor does an excellent job supporting a GPRS class 10 pulse train, drawing 1.8A for 1.1ms at 25% duty cycle. The source is current limited to 0.6A and the supercapacitor provides the 1.2A difference to achieve the peak current. At first glance the freq response of Fig 8 indicates the supercapacitor would not support a 1.1ms pulse, but the C_{eff} of 132mF coupled with the low ESR supports this pulse train with only ~45mV droop in the supply rail.

Fig 5: GS230 Pulse Response with GPRS Class 10 Pulse Train

Accurate Calculation of Voltage Drop for a Pulse Using Ceff

The combination of the method used by CAP-XX to measure ESR and effective capacitance for a given pulsewidth given in Fig 4 enable the accurate calculation of voltage drop for a pulse with current I and pulsewidth T as $V_{drop} = I \cdot [ESR + T/C_{eff}(T)]$. Using the pulse train of Fig 5 as an example, $I = 1.8A - 0.6A = 1.2A$. $T = 1.1ms$. Nominal DC capacitance = 1200mF, and from Fig 4, $C_{eff}(1.1ms) = 12\% \times 1200mF = 144mF$. Nominal ESR = 24m Ω , so $V_{drop} = 1.2A[0.024\Omega + 0.0011s/0.144F] = 38mV$. Fig 5 shows a voltage drop = 45mV verifying that the calculation is a good approximation. This avoids the need to run SPICE for a simple calculation.

DC Capacitance variation with temperature

Figure 6: Capacitance change with temperature

Fig 6 shows that DC capacitance is approximately constant with temperature.

ESR variation with temperature

Figure 7: ESR change with temperature

Fig 7 shows that ESR at -40°C is $\sim 2.2 \times$ ESR at room temp, and that ESR at 70°C is $\sim 0.8 \times$ ESR at room temperature.

Frequency Response

Fig 8: Frequency Response of Impedance (biased at 5V with a 50mV test signal)

Fig 9: Frequency Response of ESR, Capacitance & Inductance

Fig 8 shows the supercapacitor behaves as an ideal capacitor until approx 3 Hz when the magnitude no longer rolls off proportionally to $1/\text{freq}$ and the phase crosses -45° . Performance of supercapacitors with frequency is complex and the best predictor of performance is Fig 4 showing effective capacitance as a function of pulsewidth.

Leakage Current

Fig 10: Leakage Current

Fig 10 shows the leakage current for GS130 at room temperature. The leakage current decays over time, and the equilibrium value leakage current will be reached after ~120hrs at room temperature. The typical equilibrium leakage current is 1µA at room temperature. At 70°C leakage current will be ~10µA.

Charge Current

Fig 11: Charging a GS130 with low current

The corollary to the slow decay in leakage currents shown in Fig 10 is that charging a supercapacitor at very low currents takes longer than theory predicts. At higher charge currents, the charge rate is as theory predicts. For example, it should take $2.4\text{F} \times 2.2\text{V} / 0.00002\text{A} = 80\text{hrs}$ to charge a 2.4 F supercapacitor to 2.2V at 20µA, but Fig 11 shows it took 120hrs. At 100µA charging occurs at a rate close to the theoretical rate.

RMS Current

Fig 12: Temperature rise in GS230 with RMS current

Continuous current flow into/out of the supercap will cause self heating, which limits the maximum continuous current the supercapacitor can handle. This is measured by a current square wave with 50% duty cycle, charging the supercapacitor to rated voltage at a constant current, then discharging the supercapacitor to half rated voltage at the same constant current value. For a square wave with 50% duty cycle, the RMS current is the same as the current amplitude. Fig 12 shows the increase in temperature as a function of RMS current. From this, the maximum RMS current in an application can be calculated, for example, if the ambient temperature is 40°C, and the maximum desired temperature for the supercapacitor is 70°C, then the maximum RMS current should be limited to 7A, which causes a 30°C temperature increase.

CAP-XX Supercapacitors Product Guide

Refer to the package drawings in the CAP-XX Supercapacitors Product Guide for detailed information of the product's dimensions, PCB landing placements, active areas and electrical connections.

Refer to the CAP-XX Supercapacitors Product Guide for information on endurance and shelf life, transportation and storage, assembly and soldering, safety and RoHS/EREACH certification.
