Electrical Specifications

The HS103 is a single cell supercapacitor. The HS203 is a dual cell supercapacitor with two HS103 cells in series, so HS203 capacitance = Capacitance of HS103/2 and HS203 ESR = 2 x HS103 ESR.

This datasheet should be read in conjunction with the [CAP-XX Supercapacitor Product Guide](#) which contains information common to our product lines.
Definition of Terms

In its simplest form, the Equivalent Series Resistance (ESR) of a capacitor is the real part of the complex impedance. In the time domain, it can be found by applying a step discharge current to a charged cell as in Fig. 1. In this figure, the supercapacitor is pre-charged and then discharged with a current pulse, \( I = 1 \text{A} \) for duration 0.01 sec.

\[
\text{ESR} = \frac{\Delta V}{I}
\]

The ESR is found by dividing the instantaneous voltage step \((\Delta V)\) by \(I\). In this example = \((5.49 \text{V} - 5.45 \text{V})/1 \text{A} = 40 \text{m}\Omega\).

The instantaneous capacitance \((C_i)\) can be found by taking the inverse of the derivative of the voltage, and multiplying it by \(I\).

The effective capacitance for a pulse of duration \(\Delta t_n\), \(C_e(\Delta t_n)\), is found by dividing the total charge removed from the capacitor \((\Delta Q_n)\) by the voltage lost by the capacitor \((\Delta V_n)\). For constant current \(C_e(\Delta t_n) = I \times \Delta t_n/\Delta V_n\). \(C_e\) increases as the pulse width increases and tends to the DC capacitance value as the pulse width becomes very long (~10 secs). After 2msec, Fig 1 shows the voltage drop \(V_{2ms} = (5.45 \text{V} - 5.43 \text{V}) = 20 \text{mV}\). Therefore \(C_e(2ms) = 1 \text{A} \times 2\text{ms}/20\text{mV} = 100\text{mF}\). After 10ms, the voltage drop = 5.45 V – 5.388V = 62mV. Therefore \(C_e(10ms) = 1 \text{A} \times 10\text{ms}/62\text{mV} = 135\text{mF}\). The DC capacitance of an HS203 = 0.25 F. Note that \(\Delta V\), or IR drop, is not included because very little charge is removed from the capacitor during this time. \(C_e\) shows the time response of the capacitor and it is useful for predicting circuit behaviour in pulsed applications.

Measurement of DC Capacitance

Fig 2 shows the measurement of DC capacitance by drawing a constant 100mA current from a fully charged supercapacitor and measuring the time taken to discharge from 1.5V to 0.5V for a single cell, or from 3V to 1V for a dual cell supercapacitor. In this case, 
\[ C = \frac{0.1 \text{A} \times 5.71 \text{s}}{2\text{V}} = 285.5\text{mF}, \]
which is well within the 0.25F +/- 20% tolerance for an HS203 cell.

Measurement of ESR

Fig 3 shows DC measurement of ESR by applying a step load current to the supercapacitor and measuring the resulting voltage drop. CAP-XX waits for a delay of 50µs after the step current is applied to ensure the voltage and current have settled. In this case the ESR is measured as 50mV/1A = 50mΩ.
Effective Capacitance

Figure 4: Effective Capacitance

Fig 4 shows the effective capacitance for the HS103, HS203 @ 23°C. This shows that for a 1ms PW, you will measure 38% of DC capacitance or 190mF for an HS103 or 95mF for an HS203. At 10ms you will measure 67% of the DC capacitance, and at 100ms you will measure 89% of DC capacitance. C\text{effective} is a time domain representation of the supercapacitor's frequency response. If, for example, you were calculating the voltage drop if the supercapacitor was supporting 1A for 10ms, then you would use the C\text{eff}(10\text{ms}) = 67\% \text{ of DC capacitance} = 167.5\text{mF} for an HS203, so V\text{drop} = 1A \times \text{ESR} + 1A \times \text{duration}/C = 1A \times 55\text{mΩ} + 1A \times 10\text{ms} / 167.5\text{mF} = 115\text{mV}. The next section on pulse response shows how the effective capacitance is sufficient for even short pulse widths.

Pulse Response

Fig 5 shows that the HS203 supercapacitor does an excellent job supporting a GPRS class 10 pulse train, drawing 1.8A for 1.1ms at 25% duty cycle. The source is current limited to 0.6A and the supercapacitor provides the 1.2A difference to achieve the peak current. At first glance the freq response of Fig 8 indicates the supercapacitor would not support a 1ms pulse, but the C\text{eff} of 95mF coupled with the low ESR supports this pulse train with only ~80mV droop in the supply rail.

Fig 5: HS203 Pulse Response with GPRS Class 10 Pulse Train
DC Capacitance variation with temperature

Fig 6: Capacitance change with temperature

Fig 6 shows that DC capacitance is approximately constant with temperature.

ESR variation with temperature

Fig 7: ESR change with temperature

Fig 7 shows that ESR at -40°C is ~2.6 x ESR at room temp, and that ESR at 80°C is ~0.75 x ESR at room temperature.
Fig 8: Frequency Response of Impedance (biased at 5.5V with a 50mV test signal)

Fig 9: Frequency Response of ESR, Capacitance & Inductance

Fig 8 shows the supercapacitor behaves as an ideal capacitor until approx 9 Hz when the magnitude no longer rolls off proportionally to 1/freq and the phase crosses -45°. Performance of supercapacitors with frequency is complex and the best predictor of performance is Fig 4 showing effective capacitance as a function of pulsewidth.
Leakage Current

Fig 10: Leakage Current

Fig 10 shows the leakage current for HS103 at room temperature. The leakage current decays over time, and the equilibrium value leakage current will be reached after ~120hrs at room temperature. The typical equilibrium leakage current is 1µA at room temperature. At 70°C leakage current will be ~5µA.

Charge Current

Fig 11: Charging an HS103 with low current

The corollary to the slow decay in leakage currents shown in Fig 10 is that charging a supercapacitor at very low currents takes longer than theory predicts. At higher charge currents, the charge rate is as theory predicts. For example, it should take 0.5F x 2.4V / 0.00005A = 6.7hrs to charge a 0.5 F supercapacitor to 2.4V at 50µA, but Fig 11 shows it took 17hrs. At 200µA charging occurs at a rate close to the theoretical rate.
RMS Current

Fig 12: Temperature rise in HS203 with RMS current

Continuous current flow into/out of the supercapacitor will cause self-heating, which limits the maximum continuous current the supercapacitor can handle. This is measured by a current square wave with 50% duty cycle, charging the supercapacitor to rated voltage at a constant current, then discharging the supercapacitor to half rated voltage at the same constant current value. For a square wave with 50% duty cycle, the RMS current is the same as the current amplitude. Fig 12 shows the increase in temperature as a function of RMS current. From this, the maximum RMS current in an application can be calculated, for example, if the ambient temperature is 40°C, and the maximum desired temperature for the supercapacitor is 70°C, then the maximum RMS current should be limited to 4.5A, which causes a 30°C temperature increase.

CAP-XX Supercapacitors Product Guide

Refer to the package drawings in the CAP-XX Supercapacitors Product Guide for detailed information of the product’s dimensions, PCB landing placements, active areas and electrical connections, as well for information on endurance and shelf life, transportation and storage, assembly and soldering, safety and RoHS/REACH certification.
